

Invariants and Encapsulation

EECS 211

Winter 2018

A struct encapsulating a binary search tree

```
struct Tree
{
    struct Node;
    using link_t = std::shared_ptr<Node>;
    struct Node
    {
        std::string key;
        unsigned value;
        link_t left;
        link_t right;
    };
    link_t root;
    size_t size;
};
```

Invariants

Invariants are facts about a data structure that must always be true (for it to work properly).

- Operations must *preserve* invariants, and
- Consequently, operations can *rely* on invariants.

The Tree struct has invariants

For any `Tree t`,

- `t.size` needs to equal the actual number of elements
- For every node `n`, all the keys of `n.left` must be less than `n.key`
- For every node `n`, all the keys of `n.right` must be greater than `n.key`

The Tree struct has invariants

For any **Tree** `t`,

- `t.size` needs to equal the actual number of elements
- For every node `n`, all the keys of `n.left` must be less than `n.key`
- For every node `n`, all the keys of `n.right` must be greater than `n.key`

Then:

- Operations that need to know the size can safely use `t.size`.
- Operations that modify need to maintain `t.size`.
- Lookup operations can rely on ordering because modification operations maintain ordering.

A struct for rational numbers

```
// A rational number num/den  
struct Rational  
{  
    long num;  
    long den;  
};
```

Rational representation issues

There are some issues with representing rational numbers:

Rational representation issues

There are some issues with representing rational numbers:

- Do $\text{Rational}\{2, 3\}$ and $\text{Rational}\{4, 6\}$ represent the same number?

Rational representation issues

There are some issues with representing rational numbers:

- Do $\text{Rational}\{2, 3\}$ and $\text{Rational}\{4, 6\}$ represent the same number?
- What about $\text{Rational}\{2, 3\}$ and $\text{Rational}\{-2, -3\}$?

Rational representation issues

There are some issues with representing rational numbers:

- Do $\text{Rational}\{2, 3\}$ and $\text{Rational}\{4, 6\}$ represent the same number?
- What about $\text{Rational}\{2, 3\}$ and $\text{Rational}\{-2, -3\}$?
- What does $\text{Rational}\{5, 0\}$ mean?

Solution: Rational struct invariants

For any Rational r ,

- $r.den > 0$
- $\text{gcd}(r.num, r.den) == 1$

Solution: Rational struct invariants

For any `Rational` `r`,

- `r.den > 0`
- `gcd(r.num, r.den) == 1`

These two conditions ensure that:

- We don't have nonsense rationals like `Rational{5, 0}`.
- Every representable rational number has exactly one representation.

– To CLion! –
