

Control Statements and Functions

EECS 230

Winter 2017

Agenda

- Computation
 - ▶ What is computable? How best to compute it?
 - ▶ Abstractions, algorithms, heuristics, data structures
- Language constructs and ideas
 - ▶ Sequential order of execution
 - ▶ Expressions and statements
 - ▶ Selection
 - ▶ Iteration
 - ▶ Functional abstraction

You already know most of this

- You know how to do arithmetic:
 - ▶ $d = a + b \times c$

You already know most of this

- You know how to do arithmetic:
 - ▶ $d = a + b \times c$
- You know how to sequence:
 - ▶ “Open the door, then walk through.”

You already know most of this

- You know how to do arithmetic:
 - ▶ $d = a + b \times c$
- You know how to sequence:
 - ▶ “Open the door, then walk through.”
- You know how to select:
 - ▶ “If it’s raining, take an umbrella; otherwise take sunglasses.”

You already know most of this

- You know how to do arithmetic:
 - ▶ $d = a + b \times c$
- You know how to sequence:
 - ▶ “Open the door, then walk through.”
- You know how to select:
 - ▶ “If it’s raining, take an umbrella; otherwise take sunglasses.”
- You know how to iterate:
 - ▶ “Do 20 reps.”
 - ▶ “Stir until no lumps remain.”

You already know most of this

- You know how to do arithmetic:
 - ▶ $d = a + b \times c$
- You know how to sequence:
 - ▶ “Open the door, then walk through.”
- You know how to select:
 - ▶ “If it’s raining, take an umbrella; otherwise take sunglasses.”
- You know how to iterate:
 - ▶ “Do 20 reps.”
 - ▶ “Stir until no lumps remain.”
- You know how to do function calls (sort of):
 - ▶ “Go ask Alice and report back to me.”

You already know most of this

- You know how to do arithmetic:
 - ▶ $d = a + b \times c$
- You know how to sequence:
 - ▶ “Open the door, then walk through.”
- You know how to select:
 - ▶ “If it’s raining, take an umbrella; otherwise take sunglasses.”
- You know how to iterate:
 - ▶ “Do 20 reps.”
 - ▶ “Stir until no lumps remain.”
- You know how to do function calls (sort of):
 - ▶ “Go ask Alice and report back to me.”

So what I’ll be showing you is mainly syntax for things you already know.

Computation: the big picture

- Input: from keyboard, files, mouse, other input devices, the network, other programs
- Code: consumes the input and does something to produce the output
- Output: to the screen, files, printer, other output devices, the network, other programs

Expressing computation

Our job is to express computations

- simply,
- correctly, and
- efficiently.

Expressing computation

Our job is to express computations

- simply,
- correctly, and
- efficiently.

Tools:

Expressing computation

Our job is to express computations

- simply,
- correctly, and
- efficiently.

Tools:

- Divide and conquer
 - ▶ Break a big computation into several smaller ones

Expressing computation

Our job is to express computations

- simply,
- correctly, and
- efficiently.

Tools:

- Divide and conquer
 - ▶ Break a big computation into several smaller ones
- Abstraction
 - ▶ Use a higher-level concept that hides detail

Expressing computation

Our job is to express computations

- simply,
- correctly, and
- efficiently.

Tools:

- Divide and conquer
 - ▶ Break a big computation into several smaller ones
- Abstraction
 - ▶ Use a higher-level concept that hides detail
- Data organization (often key to good code)
 - ▶ Input/output formats
 - ▶ Communication protocols
 - ▶ Data structures

Expressing computation

Our job is to express computations

- simply,
- correctly, and
- efficiently.

Tools:

- Divide and conquer
 - ▶ Break a big computation into several smaller ones
- Abstraction
 - ▶ Use a higher-level concept that hides detail
- Data organization (often key to good code)
 - ▶ Input/output formats
 - ▶ Communication protocols
 - ▶ Data structures

Note the emphasis is on structure and organization

Programming language features

Each language feature exists to express a fundamental idea:

+	addition
*	multiplication
{ <i>stm stm ...</i> }	sequencing
if (<i>expr</i>) <i>stm</i> else <i>stm</i>	selection
while (<i>expr</i>) <i>stm</i>	iteration
f(x);	function call

Programming language features

Each language feature exists to express a fundamental idea:

+	addition
*	multiplication
{ <i>stm stm ...</i> }	sequencing
if (<i>expr</i>) <i>stm</i> else <i>stm</i>	selection
while (<i>expr</i>) <i>stm</i>	iteration
f(x);	function call

The meaning of each feature is simple, but we combine them into programs of arbitrary complexity.

Expressions

An expression computes a value:

```
int length = 20;           // simplest expression is a literal  
int width  = 40;
```

Expressions

An expression computes a value:

```
int length = 20;           // simplest expression is a literal
int width  = 40;
int area   = length * width; // multiplication
```

Expressions

An expression computes a value:

```
int length = 20;           // simplest expression is a literal
```

```
int width  = 40;
```

```
int area   = length * width; // multiplication
```

// as in algebra, you can compose operations

```
int average = (length + width) / 2;
```

Expressions

An expression computes a value:

```
int length = 20;           // simplest expression is a literal
```

```
int width  = 40;
```

```
int area   = length * width; // multiplication
```

// as in algebra, you can compose operations

```
int average = (length + width) / 2;
```

The usual rules of precedence apply:

$a * b + c / d$ means $(a * b) + (c / d)$, not $((a * b) + c) / d$

Expressions

An expression computes a value:

```
int length = 20;           // simplest expression is a literal
```

```
int width  = 40;
```

```
int area   = length * width; // multiplication
```

// as in algebra, you can compose operations

```
int average = (length + width) / 2;
```

The usual rules of precedence apply:

$a * b + c / d$ means $(a * b) + (c / d)$, not $((a * b) + c) / d$

When in doubt, parenthesize (but don't overdo it)

What expressions are made of

Operators and operands

- operators specify what to do
- operands specify the data to do it to

What expressions are made of

Operators and operands

- operators specify what to do
- operands specify the data to do it to

Some common operators:

Operator(s)	Meaning	bool	int	double
+, -, *, /	arithmetic		Yes	Yes
%	remainder		Yes	
==	equal	Yes	Yes	Yes
!=	not equal	Yes	Yes	Yes
<, <=, >, >=	comparisons		Yes	Yes
&&,	and, or	Yes		

Concise operators

For many binary operators, there are (roughly) equivalent more concise versions:

`a += c` means `a = a + c`

`a *= scale` means `a = a * scale`

`++a` means `a += 1`
or `a = a + 1`

Use them when they make your code clearer

Statements

A statement is one of:

- an expression followed by a semicolon,
- a declaration, or
- a *control* statement that determines control flow.

Statements

A statement is one of:

- an expression followed by a semicolon,
- a declaration, or
- a *control* statement that determines control flow.

Examples:

- `a = b;`
- `double d2 = 2.5;`
- `if (x == 2) y = 4;`
- `while (cin >> number) numbers.push_back(number);`
- `int average = (length + width) / 2;`
- `return x;`

Statements

A statement is one of:

- an expression followed by a semicolon,
- a declaration, or
- a *control* statement that determines control flow.

Examples:

- `a = b;`
- `double d2 = 2.5;`
- `if (x == 2) y = 4;`
- `while (cin >> number) numbers.push_back(number);`
- `int average = (length + width) / 2;`
- `return x;`

I don't expect you to recognize all of these...yet.

Selection

Sometimes we must choose between alternatives.

For example, suppose we want to identify the larger of two numbers. We can use an `if` statement:

```
if (a < b)
    max = b;
else
    max = a;
```

Selection

Sometimes we must choose between alternatives.

For example, suppose we want to identify the larger of two numbers. We can use an `if` statement:

```
if (a < b)
    max = b;
else
    max = a;
```

The syntax is

```
if (condition)
    statement-if-true
else
    statement-if-false
```

Sequencing

What if you want to do more than one thing in an `if`?

Sequencing

What if you want to do more than one thing in an `if`?

Use a compound statement:

```
if (a < b) {  
    max = b;  
    min = a;  
} else {  
    max = a;  
    min = b;  
}
```

Sequencing

What if you want to do more than one thing in an `if`?

Use a compound statement:

```
if (a < b) {  
    max = b;  
    min = a;  
} else {  
    max = a;  
    min = b;  
}
```

The syntax is

```
{  
    first-statement  
    second-statement  
    // etc.  
}
```

Iteration (while)

```
int i = 0;
while (i < 100) {
    cout << i << '\t' << square(i) << '\n';
    ++i;
}
```

Iteration (while)

```
int i = 0;
while (i < 100) {
    cout << i << '\t' << square(i) << '\n';
    ++i;
}
```

The syntax is

`while` (*condition*) *statement*

Iteration (for)

```
int i = 0;      // initialization
while (i < 100) {
    cout << i << '\t' << square(i) << '\n';
    ++i;      // step
}
```

This pattern—a loop with initialization and step—is so common that there's special syntax for it:

```
for (int i = 0; i < 100; ++i)
    cout << i << '\t' << square(i) << '\n';
```

Iteration (for)

```
int i = 0;           // initialization
while (i < 100) {
    cout << i << '\t' << square(i) << '\n';
    ++i;           // step
}
```

This pattern—a loop with initialization and step—is so common that there's special syntax for it:

```
for (int i = 0; i < 100; ++i)
    cout << i << '\t' << square(i) << '\n';
```

for loops are the idiomatic way to count in C++

Syntax of for

```
for (init-expr; cond-expr; step-expr)  
  body-stm
```

Syntax of for

```
for (init-expr; cond-expr; step-expr)  
  body-stm
```

means

```
init-expr;
```

```
while (cond-expr) {  
  body-stm  
  step-expr;  
}
```

Functions

But what did `square(i)` mean?

Functions

But what did `square(i)` mean?

A call to the function `square(int)`, which might be defined like

```
int square(int x)
{
    return x * x;
}
```

Functions

But what did `square(i)` mean?

A call to the function `square(int)`, which might be defined like

```
int square(int x)
{
    return x * x;
}
```

Why define a function?

Functions

But what did `square(i)` mean?

A call to the function `square(int)`, which might be defined like

```
int square(int x)
{
    return x * x;
}
```

Why define a function? We want to separate and name a computation because it...

- ...is logically separate.

Functions

But what did `square(i)` mean?

A call to the function `square(int)`, which might be defined like

```
int square(int x)
{
    return x * x;
}
```

Why define a function? We want to separate and name a computation because it...

- ...is logically separate.
- ...make the program clearer.

Functions

But what did `square(i)` mean?

A call to the function `square(int)`, which might be defined like

```
int square(int x)
{
    return x * x;
}
```

Why define a function? We want to separate and name a computation because it...

- ...is logically separate.
- ...make the program clearer.
- ...can be reused.

Functions

But what did `square(i)` mean?

A call to the function `square(int)`, which might be defined like

```
int square(int x)
{
    return x * x;
}
```

Why define a function? We want to separate and name a computation because it...

- ...is logically separate.
- ...make the program clearer.
- ...can be reused.
- ...eases testing, distribution of labor, and maintenance.

A function example

```
int square(int n) {  
    return n * n;  
}
```

```
int main () {  
    cout << sqrt(square(3) + square(4)) << '\n';  
}
```

A function example

```
int square(int n) {  
    return n * n;  
}  
  
int main () {  
    double a2 = square(3);  
    double b2 = square(4);  
    double c2 = a2 + b2;  
    double c  = sqrt(c2);  
    cout << c << '\n';  
}
```

A function example

```
int main () {  
    double a2 = square(3);  
    double b2 = square(4);  
    double c2 = a2 + b2;  
    double c  = sqrt(c2);  
    cout << c << '\n';  
}
```

```
int square(int n) {  
    return n * n;  
}
```

A function example

```
int main () {  
    double a2 = square(3);  
  
    double b2 = square(4);  
  
    double c2 = a2 + b2;  
    double c  = sqrt(c2);  
  
    cout << c << '\n';  
}
```

```
int square(int n) {  
    return n * n;  
}
```

```
int square(int n) {  
    return n * n;  
}
```

```
double sqrt(double);
```

Function definition syntax

Our function

```
int square(int x)
{
    return x * x;
}
```

is an example of

```
return-type function-name(param-type param-name,...)
{
    // code, which can use parameter(s) param-name, etc.
    return some-value;
}
```
